Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid (Art. 99(1) European patent convention).

Description

This invention relates to dispensers for viscous or pasty products such as toothpaste, of the kind having a reduceable-volume reservoir for the product, and a variable-volume pump chamber including a pump member which is operable by the user to draw product from the reservoir and subsequently expel the induced product through a suitable spout or other outlet for dispensing. For brevity, such a dispenser will hereinafter be referred to as a "pump chamber dispenser" throughout the specification and claims.

The induction and expulsion of product to and from the pump chamber of a pump chamber dispenser is achieved by the pump member, by generation of a pressure differential in the pump chamber in relation to the ambient environment. For induction of product, the pressure in the pump chamber is depressed below atmospheric pressure, and the differential pressure thereby produced causes product to be drawn from the reservoir and into the pump chamber through an entry port of the pump chamber. Correspondingly, expulsion of product from the pump chamber is caused by a superatmospheric pressure generated in the pump chamber by the pump member, which forces product to leave the pump chamber via an exit port of the pump chamber. Usually the reduceable volume reservoir is formed by a cylindrical body part of the dispenser, and a follower piston which is received in the body part and caused by differential pressure to move along the body part as dispensing proceeds. In some proposals, however, the follower piston is replaced by a flexible bag which collapses as product is being dispensed.

A pump chamber dispenser for pasty substances is known from EP-A-0144879, and shown in Figures 11 - 13 thereof is such a dispenser having a unitary body with a cylindrical part enclosing the reservoir, and an upper end part defining a discharge nozzle and mounting a unitary pumping member of elastomeric material which confines with the upper body part the variable volume pumping chamber. A recess with an axis inclined to the axis of the cylindrical body part is formed in the upper part, and the pumping member has a peripheral rim which is forced over an undercut collar provided on the upper body part around the recess. The pumping member has integral flaps for closing the inlet and outlet ports which consist of holes extending through the side walls of the recess and communicating the pumping chamber with the reservoir chamber and with the discharge nozzle, respectively. The pumping member is designed to be actuated directly by the finger of a person using the dispenser and includes a portion which is flexible and compressible to vary the volume of the pumping chamber.

The above-mentioned pump chamber dispenser suffers a number of drawbacks. The body with integral nozzle and pumping chamber recess including inlet and exit holes, all inclined to the main longitudinal axis, is complicated and correspondingly expensive and difficult to make, and the assembly of the pumping member on the body is complicated by the

need for it to be applied in a non-axial direction and after orientation, and by the need for a tight secure fit between these parts.

The present invention aims at a pump chamber dispenser which is convenient and economic to manufacture, and is effective in operation.

According to the invention there is provided a pump chamber dispenser for viscous or pasty product comprising a body including a tubular side wall and an end wall panel integral with the side wall, a closed reservoir chamber within the body for receiving viscous or pasty product to be dispensed, the chamber being defined partly by said end wall panel and being reduceable in volume as product is discharged therefrom, and a unitary pumping member of elastomeric material mounted on the end wall panel outside of the reservoir chamber and confining with the end wall panel a variable volume pump chamber, the pumping member including integral inlet and exit valve elements for controlling respectively an inlet port for conducting product to the pumping chamber from the reservoir chamber and an exit port for conducting product from the pumping chamber to a discharge nozzle, wherein:

the end wall panel has a generally annular projection directed away from the reservoir chamber and extending around an axis substantially parallel to the longitudinal axis of the body;

the pumping member has a domed portion and inner and outer coaxial skirts extending from the edge of the domed portion and forming the inlet and exit valve elements, respectively, said skirts lying against radially inner and outer surfaces of said projection;

the inlet port extends through the said radially inner surface of the projection and is closable by the inner skirt;

a passage formed within the projection communicates the inlet port with the reservoir chamber;

a recess in the end wall panel extends across the projection and defines the exit port, the exit port being in communication with the pumping chamber and opening at the radially outer surface of the projection at a position to be closable by the outer skirt; and

a cover member is attached to the body and defines said discharge nozzle, the cover member being arranged to enclose the pumping member and having a movable part for acting on the domed portion of the pumping member to reduce the volume of the pumping chamber for dispensing.

With a pump dispenser embodying the invention the body can be easily produced, especially by injection moulding. The discharge nozzle is provided by a cover member engaged in an operative position with the body, preferably by a snap fit connection, after the pumping member has been positioned on the body. The cover member can also serve to maintain the pumping member in operative combination with the body so that a tight force fit between them is no longer necessary. The pumping member is easily located on the body by moving the two skirts down on to the projection in the axial direction. In a preferred construction the inner and outer skirts are peripherally continuous and the pumping member is

rotationally symmetrical, providing further improvement by eliminating the need for the pumping member to be oriented angularly with respect to the body. Each of the skirts is preferably non-convergent towards its free edge, and in a particular embodiment the skirts are substantially parallel to the longitudinal axis of the body. The inlet and exit ports are readily formed when making the body, as can the passage which connects the inlet port with the reservoir chamber. In a preferred construction the passage is defined by a groove which is open to the reservoir chamber. The groove avoids a narrow duct which could constrict flow of the viscous product to the pumping chamber, and can assist in conducting product to the inlet port from different regions around the axis of the dispenser. Finally, it may be mentioned that by virtue of the cover member having a part, such as a hinged portion or button, which acts on the pumping member, during operation the dispenser may have a more positive feel than a dispenser in which the pumping member is deformed directly by the finger of a user. Furthermore, by including an actuating part for acting on the pumping member greater choice is available for selecting the particular manner of actuation, e.g. by push button, pivoting lever, deformable diaphragm, etc.

In order that the invention may be more fully understood, two embodiments thereof will now be described, by way of example, with reference to the accompanying drawings in which:

Figure 1 shows a first pump chamber dispenser in accordance with the invention, as seen in central vertical section;

Figure 2 is a plan view of the body of the dispenser of Figure 1, showing detail of the closure panel; and

Figure 3 is a view similar to Figure 1 of a second pump chamber dispenser in accordance with the invention, showing the top part only of the dispenser.

Referring now to Figure 1 of the drawings, a pump chamber dispenser for toothpaste or like viscous or pasty product has an injection-moulded plastics body 10 arranged to stand upright on a flared standing rim 12 at its bottom end as shown. Above the rim the body is cylindrical and receives an injection-moulded plastics follower piston 14 which is slidable along its bore 16. The top end of the body is integrally closed by a contoured end wall or closure panel 18. The closure panel 18 is formed with an aperture 20 forming an inlet port for the pump chamber 21 of the dispenser as is later to be described. The body 10 and the follower piston 14 together form a reduceable-volume reservoir chamber in which the product is held and which is denoted generally by reference numeral 22.

The follower piston 14 comprises a central panel 23 formed on its underside with a stiffening collar 24 which also assists the initial insertion of the piston into the body after filling with product. For engaging the body bore 16 the piston has a flexible skirt 26 which is carried from the periphery of the central panel 23 and has leading and trailing feather

edges 28, 30 which engage the bore 16 resiliently so as to prevent any leakage of air past the piston from outside when the pump chamber 21 is being recharged with product after a dispensing stroke. At its centre the panel 23 is formed with a boss 32 which is complementary to a corresponding boss 34 of the body closure panel 18 so as to minimise the amount of product residue left in the empty dispenser underneath the boss 34.

As can best be seen in Figure 2 which shows it in plan view from above, the body closure panel 18 includes, in addition to the upstanding central boss 34, a further, generally circular, upstanding projection 36 which extends concentrically around the boss 34. The projection 36 is hollow due to a groove 37 which is formed in the underside of the closure panel and is open to the product reservoir 22. The projection has inner and outer concentric cylindrical walls 38, 40, and a rounded top wall 42.

The previously mentioned aperture 20 is formed at the junction of the inner wall 38 and the rounded top wall 42, and is located in diametric opposition to a recess or discontinuity 44 of the projection 36 which extends through approximately 15° of arc and serves to define an outlet port, as will become clear.

The ends of the projection 36 at the discontinuity 44 are substantially closed by end walls 46, of which one is visible full-face in Figure 1. The annular portion 48 of the closure panel 18 lying between the boss 34 and the projection 36 is plane except at the discontinuity 44; there, the closure panel is formed with a well 50 which extends, below the level of the annulus 48, from the boss 34 to outwardly beyond the circular locus of the inner wall 38. The well has a base angle 51, and side walls 52 (Figure 1) which form plane continuations of the end walls 46 of the projection 36.

Outside the well the closure panel 18 rises above the level of the annulus 48 to form a shallow and radially narrow continuation 53 of the projection 36 between the end walls 46, including a shallow portion 40A of the outer wall 40. The continuation 53 thus forms a sill over which product can pass for dispensing as is later described.

Referring again to Figure 1, the part of the closure panel 18 comprises of the annulus 48 and the boss 34 forms the base of the pump chamber 21 for the dispenser. The pump chamber is otherwise formed by a unitary pump member 54 which is moulded from a suitable elastomeric material such as silicon rubber and is rotationally symmetrical. As can clearly be seen in Figure 1, the member 54 comprises a central dome 56 generally of hemispherical shape and overlying the annulus 48 and boss 34, and a bifurcated depending skirt formed of inner and outer peripherally continuous and radially spaced, equal length skirts 58, 60. In the interests of clarity the bifurcated skirt as such is not individually referenced. The skirts 58, 60 are integrally joined at their top edges by a rounded portion 62 of the pump member, which is moulded to conform in cross-section to the rounded top wall 42 of the projection 36.

The length of the skirts 58, 60 is slightly less than the height of the walls 38, 40 of the projection 36.

The portion 62 of the pump member merges with the base of the dome 56, so that the skirts 58, 60 - (in particular the inner skirt 58) - are disposed radially outside the dome; this allows the dome to be freely compressed for dispensing, as is later to be described.

The pump member 54 is assembled to the body 10 by sliding the skirts down over the projection 36, with inner skirt 58 abutting the inner wall 38 of the projection 36, with outer skirt 60 lightly stretched elastically around the outer wall 40 of the projection, and with its rounded portion 62 in closed conformity with the top wall 42 of the projection. The bifurcated skirt of the pump member 54 thus separately closes both the aperture 20 and the discontinuity 44 of the projection 36, whilst the well 50 communicates the pump chamber 21 with the discontinuity 44 beneath the inner skirt 58.

A moulded plastics cover 64 is snap-engaged permanently on to the body 10 and retained there by a peripheral bead 66. It encloses the pump member 54 so as substantially to prevent inadvertent operation of the dispenser, and provides an upstanding hollow spout 68 through which product may leave the dispenser for deposition on to, for example, a toothbrush. For that purpose the bottom, proximal end of the spout 68 is located over the outside of the outer skirt 60 at the discontinuity 44, as is indicated by the broken line in Figure 2. A part 61 of the spout engages the exterior of the rounded portion 60 so as to control the flow of product past the skirt 60, said part holding the skirt 60 against the projection 36 at either side of the discontinuity 44 forming what may be considered as the exit port of the pump chamber.

Although the elasticity of the outer skirt 60, together with the engagement by the actuator 70 and by the portion 61 of the spout 68, may be sufficient to retain the pump member 54 satisfactorily on the projection 36, for additional security axially extending, radially projecting ribs 65 - two of which are shown - are moulded on the inside surface of the cover 64 so as with their free edges to engage the exterior of the outer skirt 60 and to pinch the skirt against the underlying outer wall 40 of the projection.

The dispenser is arranged to be operated by finger pressure of the user, and accordingly has a moulded plastics piston actuator 70 held captive for vertical sliding movement by the cover 64, with its rounded lower end 72 in central engagement with the top of the dome 56 of the pump member 54, and with its upper end accessible to the user. By virtue of its natural resilience, the pump member biases the actuator upwardly against an annular limit stop 74 which defines the retracted, non-operative position of the actuator as shown. For ease of moulding, the actuator is formed of upper and lower parts 76, 78 which are snap-engaged together and secured by a bead 79 on the upper part.

The dispenser is charged with product through the bottom end of the body 10 with the follower piston 14 absent. The piston 14 is then pushed into the body and up to the product, suitable means, e.g. longitudinally extending grooves 80 formed along the

base 16 at the lower end of the body, being provided for venting the body of trapped air as the piston 14 is being inserted. If desired, one or more priming operations of the actuator may be performed at this stage.

For use, the consumer depresses the actuator 70 repeatedly as required, so as to dispense metered amounts of the product through the spout 68. On each downward stroke of the actuator the dome 56 of the pump member 54 is compressed, so pressurising product already in the pump chamber 21. Product is therefore forced from the pump chamber along the well 50 and into the discontinuity 44 of the projection 36; it then forces the outer skirt 60 of the pump member locally away from the shallow wall portion 40A of the sill 53, so enabling the product to pass over the sill and into the spout 68 for dispensing. During this time the inner skirt 58 closes the inlet aperture 20 against any escape of product back into the product reservoir, it being understood that the greater the pressure of product in the pump chamber the more firmly the inner skirt will be forced against the projection 36 to form the desired seal against product flow in the reverse direction. The boss 34 ensures a free passage for product to enter the well 50 around the whole periphery of the dispenser, by limiting the possible compression of the pump member by the user. If desired, for different applications, the height of the boss 34 may be varied to change the volume of product delivered by each operation of the dispenser.

After each dispensing stroke the user releases the actuator 70, whereupon the pump member 54 reverts resiliently to its original shape, thereby forcing the actuator upward to its retracted position shown and at the same time creating a subatmospheric pressure in the pump chamber. This reduced pressure creates a differential pressure across the inner skirt at the inlet aperture 20, so forcing the skirt to move locally away from the projection 36 in a radially inward direction, and allowing product to pass beneath the inner skirt and to enter the pump chamber from the product reservoir.

In this way the pump chamber is replenished with product from the product reservoir. Any substantial "suck-back" of product down the spout 68 during this time is prevented by sealing engagement of the outer skirt 60 with the wall portion 40A of the projection 36, although a small degree of suck-back may be desirable to prevent dribbling.

In known manner of piston 14 is forced by atmospheric pressure to move along the body so as to remain in full contact with the product as dispensing proceeds. If desired, a board or plastics disc 82 may be snap-engaged into the standing rim 12 as shown so as to prevent dust and other foreign matter from entering the body behind the piston.

In a possible modification of the dispenser shown in Figures 1, 2 the inner skirt 58 is reduced in height so as to terminate at a substantial distance above the plane of the annulus 48; the well 50 is then omitted.

The embodiment of the invention shown in Figure 3 has many similarities to the embodiment of Figures 1 and 2, and the same reference numerals as be-

fore, prefixed with the numeral 1, are generally used to indicate like or equivalent parts.

In Figure 3 the pump member 154 is again unitary and generally dome-shaped, and forms a pump chamber 121 with the closure panel 118 of the dispenser body 110 (only the top part of which is shown). As with the first embodiment, the pump member has a central dome 156 and a bifurcated peripheral skirt formed with inner and outer skirts 158, 160, the inner skirt being arranged to form an entry valve for the pump chamber and the outer skirt likewise being arranged to form an exit valve for the pump chamber.

The inner skirt 158 is frustoconical and is moulded to extend inwardly and downwardly in relation to the pump chamber 121. When the pump member is assembled to the body 110 as shown, the inner skirt lies against the frustoconical upper surface 117 of a solid, generally annular projection 136 moulded as part of the body closure panel 118.

The projection 136 is formed with a passage 120 leading to the entry port of the pump chamber 121 and accordingly arranged to communicate the pump chamber with the variable-volume reservoir 122 of the dispenser when the inner skirt is raised; to assist moulding the passage 120 is perpendicular to the closure panel 118 so as to be directed axially of the dispenser. Diametrically opposite the passage 120 the projection is formed with a discontinuity 144 by which product can leave the pump chamber via the exit valve formed by the outer skirt 160. The sides of the discontinuity are formed by spaced vertical faces 146 of which one can be seen in Figure 3.

The pump member is enclosed by an upper cover 164 providing a dispensing spout 168 which projects horizontally from the side of the dispenser. The cover 164 is moulded integrally with the body 110 and attached by an integral hinge 111 which is located underneath the spout 168. It provides the actuator 170 for the dispenser and accordingly is articulated at a further integral hinge 165 formed across its top panel. The actuator portion 170 of the cover is biased by the hinge 165 to lie against the underlying pump member 154, and for dispensing is depressed by the user so as to pivot downwardly about the hinge.

In addition to the upper cover 164, a lower cover part in the form of a security member 181 is moulded integrally with the body 110 and attached by a further integral hinge 182. The security member has a ring portion 183 which is sleeved over the outer skirt 160 of the pump member 154 to hold the pump member in position on the body with the assistance of a bead 184 on the outer skirt.

The formation of the cover 164 (including the actuator portion 170) and the security member 181 integrally with the body 110 avoids any requirement for those items to be orientated angularly in relation to one another before assembly. The cover, security member and body are moulded so as to be in an extended, generally horizontal, relation. For assembly the pump member is located on the projection 136 as shown, the security member is then swung into its required position from the left, and the cover 164

with the actuator portion 170 is subsequently swung into position from the right.

In contrast with the first embodiment, however, the pump member 154 does require orientation in relation to the body 110; it is rotationally asymmetrical, having a discontinuity in its inner skirt 158 corresponding to the discontinuity 144 of the projection 136, and having a flap 185 corresponding in angular position to this discontinuity on the outside of the pump member and arranged to prevent product from escaping into the cover 164 when on its way to the dispensing spout 168.

It will be understood from the foregoing that the pump member 54, 154 of each of the described embodiments provides not only for pumping product from the associated product reservoir to the dispensing spout of the dispenser, but it also provides flap valves by which the inlet and exit ports of the pump chambers are controlled. By suitable choice of the individual thicknesses of the pump member at its dome portion and at its inner and outer skirts, the ability of the pump member to perform the different functions required of it can be optimised, and the dispenser can be adapted for products having widely different flow characteristics. Moreover, the pump member is of simple shape and is correspondingly cheap to mould, and in the embodiment of Figure 1 it is rotationally symmetrical and does not require angular orientation before assembly.

The pump member of a dispenser according to the invention may have configurations other than the particular configurations shown and described for the members 54, 154. Preferably, as in the embodiment of Figures 1 and 2, the pump member is rotationally symmetrical so as not to require orientation for assembly.

Claims

1. A pump chamber dispenser for viscous or pasty product comprising a body (10; 110) including a tubular side wall and an end wall panel (18; 118) integral with the side wall, a closed reservoir chamber (22; 122) within the body for receiving viscous or pasty product to be dispensed, the chamber being defined partly by said end wall panel and being reduceable in volume as product is discharged therefrom, and a unitary pumping member (54; 154) of elastomeric material mounted on the end wall panel outside of the reservoir chamber and confining with the end wall panel a variable volume pump chamber (21; 121), the pumping member including integral inlet and exit valve elements (58, 60; 158, 160) for controlling respectively an inlet port (20; 120) for conducting product to the pumping chamber from the reservoir chamber and an exit port (44; 144) for conducting product from the pumping chamber to a discharge nozzle (68; 168), characterised in that:

the end wall panel (18; 118) has a generally annular projection (36; 136) directed away from the reservoir chamber and extending around an axis substantially parallel to the longitudinal axis of the body;

the pumping member (54; 154) has a dome portion (56; 156) and inner and outer coaxial skirts (58, 60;

158, 160) extending from the edge of the dome portion and forming the inlet and exit valve elements, respectively, said skirts lying against radially inner and outer surfaces of said projection (36; 136);

the inlet port extends through the said radially inner surface of the projection and is closable by the inner skirt (58; 158);

a passage formed within the projection communicates the inlet port with the reservoir chamber;

a recess (44; 144) in the end wall panel extends across the projection and defines the exit port, the exit port being in communication with the pumping chamber and opening at the radially outer surface of the projection at a position to be closable by the outer skirt (60; 160); and

a cover member (64; 164) is attached to the body (10; 110) and defines said discharge nozzle (68; 168); the cover member being arranged to enclose the pumping member and having a movable part (70; 170) for acting on the domed portion of the pumping member to reduce the volume of the pumping chamber for dispensing.

2. A pump chamber dispenser according to claim 1, wherein the inner skirt (58; 158) extends continuously between the pumping chamber and the exit port, but the exit port communicates with the pumping chamber at a level beyond the free edge of the inner skirt (58; 158).

3. A pump dispenser according to claim 1 or 2, wherein the inner and outer skirts (58, 60; 158, 160) are peripherally continuous and the pumping member (54) is rotationally symmetrical.

4. A pump chamber dispenser according to claim 1, 2 or 3, wherein each skirt (58, 60; 158, 160) is non-convergent towards the free edge thereof.

5. A pump chamber dispenser according to claim 4, wherein the skirts (58, 60; 158, 160) are substantially parallel to the longitudinal axis of the body (10; 110).

6. A pump chamber dispenser according to any one of claims 1 to 5, wherein the passage is defined by a groove (37) formed along the projection (36; 136) and open to the reservoir chamber.

7. A pump chamber dispenser according to claim 6, wherein clamping means (65; 183) engages and clamps the outer skirt (60; 160) against said radially outer surface, said clamping means being moved into a position of engagement with the outer skirt only after the pumping member (54; 154) has been mounted on the end wall panel (18; 118) whereby not to impede the mounting of the pumping member onto the annular projection (36; 136).

8. A pump chamber dispenser according to claim 7 wherein the clamping means (65) is provided on the cover member (64) and presses said outer skirt (60) into sealing abutment with said radially outer surface of the projection (36) at either side of said exit port.

9. A pump chamber dispenser according to any one of claims 1 to 8, wherein the cover member (64) has a snap fit attachment to the body.

10. A pump chamber dispenser according to claim 1, 2 or 3, wherein the outer skirt (160) of the pumping member (154) is held in engagement with the projection (136) by a member (181) moved into cooperation

with the outer skirt after the pumping member has been mounted on the end wall panel and before the cover member (164) is positioned to enclose the pumping member.

11. A pump chamber dispenser according to claim 1, 2, 3, or 10 wherein the cover member (164) is integral with the body and attached thereto by an integral hinge (111).

Revendications

1. Distributeur à chambre de pompe, pour produit visqueux ou pâteux, comprenant: un corps (10; 110) incluant une paroi latérale tubulaire et un panneau-paroi d'extrémité (18; 118) d'un seul tenant avec la paroi latérale, une chambre-réservoir fermée (22; 122) située à l'intérieur du corps, pour recevoir du produit visqueux ou pâteux à distribuer, cette chambre étant délimitée en partie par ledit panneau-paroi d'extrémité et pouvant avoir son volume réduit lorsque du produit en est évacué, et un organe de pompage unitaire (54; 154) en matière élastomère, monté sur le panneau-paroi d'extrémité, à l'extérieur de la chambre-réservoir et confinant, avec le panneau-paroi d'extrémité, une chambre de pompe à volume variable (21; 121), l'organe de pompage incluant des éléments de valve d'entrée et de sortie (58, 60; 158, 160) d'un seul tenant avec lui, pour commander respectivement un passage d'entrée (20; 120) pour conduire à la chambre de pompage du produit venant de la chambre-réservoir, et un passage de sortie (44; 144) pour conduire du produit de la chambre de pompage à un ajutage de décharge (68; 168), caractérisé en ce que:

le panneau-paroi d'extrémité (18; 118) possède un saillant de forme générale annulaire (36; 136) dirigé dans le sens s'éloignant de la chambre-réservoir et s'étendant autour d'un axe sensiblement parallèle à l'axe longitudinal du corps;

l'organe de pompage (54; 154) possède une partie en forme de dôme (56; 156) et des jupes intérieure et extérieure coaxiales (58, 60; 158, 160) qui s'étendent depuis le bord de la partie en forme de dôme et forment respectivement les éléments de valve d'entrée et de sortie, lesdites jupes s'appliquant contre des surfaces radialement intérieure et extérieure dudit saillant (36; 136);

le passage d'entrée s'étend au travers de ladite surface radialement intérieure du saillant et peut être fermé par la jupe intérieure (58; 158);

un passage formé dans le saillant met le passage d'entrée en communication avec la chambre-réservoir;

un évidement (44; 144) dans le panneau-paroi d'extrémité s'étend en travers du saillant et définit le passage de sortie, le passage de sortie étant en communication avec la chambre de pompage et s'ouvrant à la surface radialement extérieure du saillant, à une position permettant la fermeture par la jupe extérieure (60; 160); et

un organe couvercle (64; 164) est attaché au corps (10; 110) et définit ledit ajutage de décharge (68; 168), l'organe couvercle étant agencé pour enclore l'organe de pompage et ayant une partie mobile (70; 170) pour agir sur la partie en forme de

dôme de l'organe de pompage, pour réduire le volume de la chambre de pompage aux fins de distribution.

2. Distributeur à chambre de pompe selon revendication 1, dans lequel la jupe intérieure (58; 158) s'étend de manière continue entre la chambre de pompage et le passage de sortie, mais le passage de sortie communique avec la chambre de pompage à un niveau en dessous du bord libre de la jupe intérieure (58; 158).

3. Distributeur à chambre de pompe selon revendication 1 ou 2, dans lequel les jupes intérieure et extérieure (58, 60; 158, 160) sont périphériquement continues et l'organe de pompage (54) est doté d'une symétrie de rotation.

4. Distributeur à chambre de pompe selon revendication 1, 2 ou 3, dans lequel chaque jupe (58, 60; 158, 160) est non-convergente vers son bord libre.

5. Distributeur à chambre de pompe selon revendication 4, dans lequel les jupes (58, 60; 158, 160) sont sensiblement parallèles à l'axe longitudinal du corps (10; 110).

6. Distributeur à chambre de pompe selon l'une quelconque des revendications 1 à 5, dans lequel le passage est défini par une gorge (37) formée le long du saillant (36; 136) et ouverte vers la chambre-réservoir.

7. Distributeur à chambre de pompe selon revendication 6, dans lequel des moyens d'attache par serrage (65; 183) sont en condition d'engagement avec la jupe extérieure (60; 160) et la serrent contre ladite surface radialement extérieure, lesdits moyens d'attache par serrage étant déplacés à une position d'engagement avec la chemise extérieure qu'après que l'organe de pompage (54; 154) a été monté sur le panneau-paroi d'extrémité (18; 118) de manière à ne pas empêcher le montage de l'organe de pompage sur le saillant annulaire (36; 136).

8. Distributeur à chambre de pompe selon revendication 7, dans lequel les moyens d'attache par serrage (65) sont prévus sur l'organe couvercle (64) et pressent ladite chemise extérieure (60) pour la mettre en aboutement étanche avec ladite surface radialement extérieure du saillant (36), en l'un et l'autre côtés dudit passage de sortie.

9. Distributeur à chambre de pompe selon l'une quelconque des revendications 1 à 8, dans lequel l'organe couvercle (64) est attaché au corps par adaptation et enclenchement.

10. Distributeur à chambre de pompe selon revendications 1, 2 ou 3, dans lequel la jupe extérieure (160) de l'organe de pompage (154) est maintenue en condition d'engagement avec le saillant (136) par un organe (181) déplacé en coopération avec la jupe extérieure après que l'élément de pompage a été monté sur le panneau-paroi d'extrémité et avant que l'organe couvercle (164) soit positionné pour enfermer l'organe de pompage.

11. Distributeur à chambre de pompe selon revendication 1, 2, 3 ou 10, dans lequel l'organe couvercle (164) est d'un seul tenant avec le corps auquel il est attaché par une charnière d'un seul tenant (111).

Patentansprüche

1. Pumpkammerabgabegerät für viskose oder pastöse Erzeugnisse, enthaltend einen Körper (10; 110) mit einer tubusförmigen Seitenwand und einer Stirnwandplatte (18; 118), die mit der Seitenwand integral vereinigt ist, eine geschlossene Vorratskammer (22; 122) innerhalb des Körpers zur Aufnahme eines abzugebenden viskosen oder pastösen Erzeugnisses, welche Kammer teilweise durch die Stirnwandplatte begrenzt und im Volumen reduzierbar ist, wenn das Erzeugnis daraus abgegeben wird, und ein einstückiges Pumpelement (54; 154) aus elastomärem Material, das an der Stirnwandplattenaußenseite der Vorratskammer befestigt ist und mit der Stirnwandplatte eine Pumpkammer (21; 121) variablen Volumens begrenzt, wobei das Pumpelement integrale Einlaß- und Auslaßventilelemente (58, 60; 158, 160) zum Steuern einer Einlaßöffnung (20; 120) zum Einleiten von Erzeugnis aus der Vorratskammer in die Pumpkammer bzw. eine Auslaßöffnung (44; 144) zum Ausleiten von Erzeugnis aus der Pumpkammer zu einer Abgabedüse (68; 168) aufweist, dadurch gekennzeichnet, daß:

die Stirnwandplatte (18; 118) einen im wesentlichen ringförmigen Vorsprung (36; 136) aufweist, der von der Vorratskammer weggerichtet ist und sich um eine Achse erstreckt, die im wesentlichen zur Längsachse des Körpers verläuft;

das Pumpelement (54, 154) einen kuppelförmigen Abschnitt (56; 156) und innere und äußere koaxiale Schürzen (58, 60; 158, 160) aufweist, die sich vom Rand des kuppelförmigen Abschnitts erstrecken und die Einlaß- und Auslaßventilelemente bilden und die an radial inneren und äußeren Oberflächen des Vorsprungs (36; 136) anliegen;

die Einlaßöffnung sich durch die radial innere Oberfläche des Vorsprungs erstreckt und durch die innere Schürze (58; 158) verschließbar ist; ein Durchlaß in dem Vorsprung ausgebildet ist, der die Einlaßöffnung mit der Vorratskammer verbindet;

eine Ausnehmung (44; 144) in der Stirnwandplatte sich über den Vorsprung erstreckt und die Auslaßöffnung bildet, die mit der Pumpkammer in Verbindung ist und sich an der radial äußeren Oberfläche des Vorsprungs an einer Position öffnet, um durch die äußere Schürze (60; 160) verschließbar zu sein; und

ein Deckelelement (64; 164) ist an dem Körper (10; 110) befestigt und bildet die Auslaßdüse (68; 168), wobei das Deckelelement dazu eingerichtet ist, das Pumpelement zu umschließen, und ein bewegliches Teil (70; 170) aufweist, um auf den kuppelförmigen Abschnitt des Pumpelements einzuwirken, um das Volumen der Pumpkammer zur Abgabe zu reduzieren.

2. Pumpkammerabgabegerät nach Anspruch 1, bei dem die innere Schürze (58; 158) sich durchgehend zwischen der Pumpkammer und der Auslaßöffnung erstreckt, jedoch die Auslaßöffnung mit der Pumpkammer an einem Niveau jenseits des freien Randes der inneren Schürze (58; 158) in Verbindung steht.

3. Pumpkammerabgabegerät nach Anspruch 1 oder 2, bei dem die inneren und äußeren Schürzen (58, 60; 158, 160) in Umfangsrichtung durchgehend sind und das Pumpelement (54) rotationssymmetrisch ist. 5
4. Pumpkammerabgabegerät nach Anspruch 1, 2 oder 3, bei dem jede Schürze (58, 60; 158, 160) gegen ihren freien Rand nicht-konvergent ist.
5. Pumpkammerabgabegerät nach Anspruch 4, bei dem die Schürzen (58, 60; 158, 160) im wesentlichen parallel zur Längsachse des Körpers (10; 110) sind. 10
6. Pumpkammerabgabegerät nach einem der Ansprüche 1 bis 5, bei dem der Durchlaß durch eine Rille (37) gebildet ist, die längs des Vorsprungs (36; 136) ausgebildet und gegen die Vorratskammer offen ist. 15
7. Pumpkammerabgabegerät nach Anspruch 6, bei dem eine Klemmeinrichtung (65; 183) auf die äußere Schürze (60; 160) einwirkt und sie gegen die radial äußere Oberfläche klemmt, welche Klemmeinrichtung in eine Eingriffsposition mit der äußeren Schürze nur bewegt wird, nachdem das Pumpelement (54; 154) an der Stirnwandplatte (18; 118) montiert worden ist, um dadurch die Montage des Pumpelements an dem ringförmigen Vorsprung (36; 136) nicht zu stören. 20 25
8. Pumpkammerabgabegerät nach Anspruch 7, bei dem die Klemmeinrichtung (65) an dem Deckelement (64) ausgebildet ist und die äußere Schürze (60) in abdichtende Anlage an die radial äußere Oberfläche des Vorsprungs (36) zu beiden Seiten der Auslaßöffnung drückt. 30
9. Pumpkammerabgabegerät nach einem der Ansprüche 1 bis 8, bei den das Deckelement (64) eine Schnappbefestigung an dem Körper aufweist. 35
10. Pumpkammerabgabegerät nach Anspruch 1, 2 oder 3, bei dem die äußere Schürze (160) des Pumpelements (154) von einem Element (181) in Eingriff mit dem Vorsprung (136) gehalten wird, das in Zusammenwirkung mit der äußeren Schürze bewegt wird, nachdem das Pumpelement an der Stirnwandplatte angebracht worden ist und bevor das Deckelement (164) so positioniert wird, daß es das Pumpelement umschließt. 40 45
11. Pumpkammerabgabegerät nach Anspruch 1, 2, 3 oder 10, bei dem das Deckelement (164) integral mit dem Körper ist und daran durch ein integrales Gelenk (111) befestigt ist. 50
